

Experiment 2:

Implement a basic finite state automaton that recognizes a specific language or pattern. In this example, we'll create a simple automaton to match strings ending with 'ab' using python.

Program:

```
def fsa(string):  
    if len(string) >= 2 and string[-2:] == "ab":  
        return True  
    return False  
  
s = input("Enter a string: ")  
  
if fsa(s):  
    print("Accepted")  
else:  
    print("Rejected")
```

Output:

The screenshot shows a code editor with a Python script. The script defines a function `fsa(string)` that checks if a string ends with "ab". It then prompts the user to enter a string. The output shows the user entered "aaaab", and the program printed "Accepted".

```
def fsa(string):  
    if len(string) >= 2 and string[-2:] == "ab":  
        return True  
    return False  
  
s = input("Enter a string: ")  
  
if fsa(s):  
    print("Accepted")  
else:  
    print("Rejected")  
  
... Enter a string: aaaab  
Accepted
```
